Abstract

2D-Pnictogens (P, As, Sb and Bi) have gained increasing attention due to their semiconducting behavior, with thickness-dependent band gaps that can be modulated by strain, doping or chemical functionalization, which can be useful for fabricating optoelectronic devices. Additionally, these 2D-materials offer unique photonic, catalytic, magnetic, and electronic properties. [1] Within this group, antimonene shows exceptional physico-chemical properties. Although some of its theoretically-predicted remarkable properties have already been experimentally demonstrated, others remain a challenge to corroborate because of the absence of a suitable synthetic method to produce the required high-quality material. [2] Antimonene can be isolated using top-down and bottom-up approaches. [3,4] A new bottom-up approach has been recently reported, involving a solution phase synthesis of well-defined hexagonal few-layer antimonene via anisotropic growth, [5] which has facilitated large-scale production of this material. In this context, we optimized the synthetic parameters for the production of high quality few-layer antimonene hexagons, and their implementation in a large-scale manufacturing process under continuous-flow conditions to pave the way for optoelectronic device fabrication. [6]
