Layers of two-dimensional materials stacked with a small twist-angle give rise to beating periodic patterns on a scale much larger than the original lattice, referred to as a "moiré superlattice". As the twist angle approaches ~ 1.08 degree, isolated flat-bands emerge near zero energy. Correlated superconducting and insulating states were reported near the half-filling of such flat-bands. In this talk, we will discuss a higher-order moiré superlattice of moiré superlattices in a twisted-trilayer graphene architecture [1]. We report transport signatures of superconducting and correlated insulating states near the half filling of the moiré of moiré superlattice, at an extremely low carrier density on the order of $\sim 10^{10}$ cm⁻². We also show that the temperature dependence of $\nu = -4$ and $\nu = 4$ states are semi-metallic, distinct from the insulating behavior in twisted bilayer systems, demonstrating that moiré superconductivity may emerge from continuous and non-isolated flat-bands. Towards further understanding and utilizing the rich underlying physics in twisted-trilayer-graphene, we will also talk about our recent effort in building gate-defined nanostructures to locally manipulate charge carriers with electrostatics in graphene [2].
